Life is built on protein and small molecule interactions

The Structures of the Citric Acid Cycle

Also known as the Krebs cycle or the tricarboxylic acid cycle, the citric acid cycle is at the center of cellular metabolism. It plays a starring role in both the process of energy production and biosynthesis. The cycle finishes the sugar-breaking job started in glycolysis and fuels the production of ATP in the process. It is also a central hub in biosynthetic reactions, providing intermediates that are used to build amino acids and other molecules. Citric acid cycle enzymes are found in all cells that use oxygen, and even in some cells that don't.

Eight Reactions

The eight reactions of the citric acid cycle use the small molecule oxaloacetate as a catalyst. The cycle starts by addition of an acetyl group to oxaloacetate, then, over the course of eight steps, the acetyl group is completely broken apart, finally restoring the oxaloacetate molecule for another round.

Small molecules are:

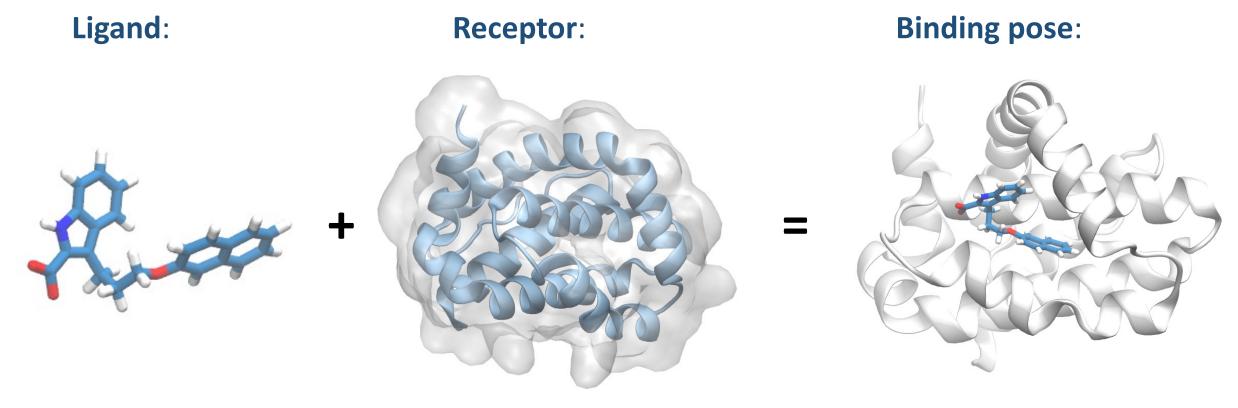

- substrates of enzymes
- Inhibitors or activators
- Co-factors

And play an important role in life.

Accurate interaction prediction is essential.

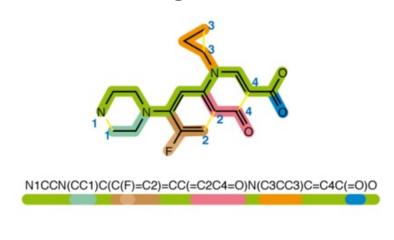

What is docking?

The process of predicting a stable 3D geometry of an interacting pair of molecules – a binding mode/pose.

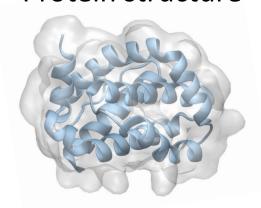

Typical workflow

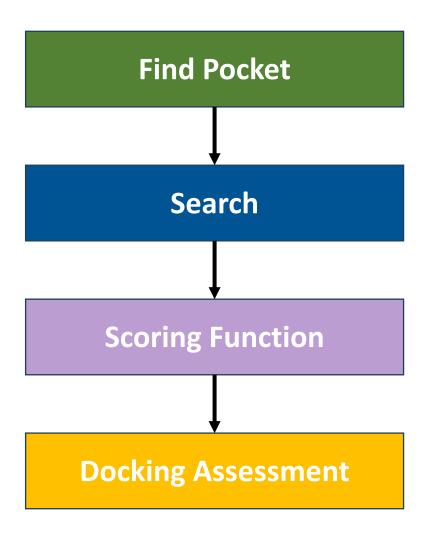

1-D or 2-D ligand structure

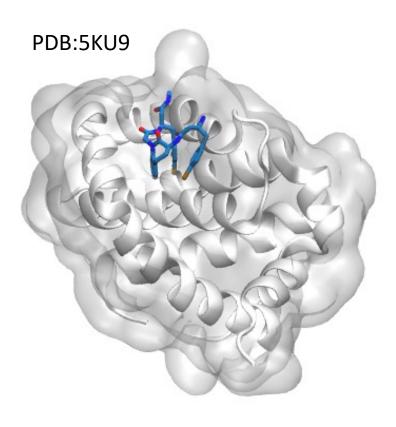

Protein structure

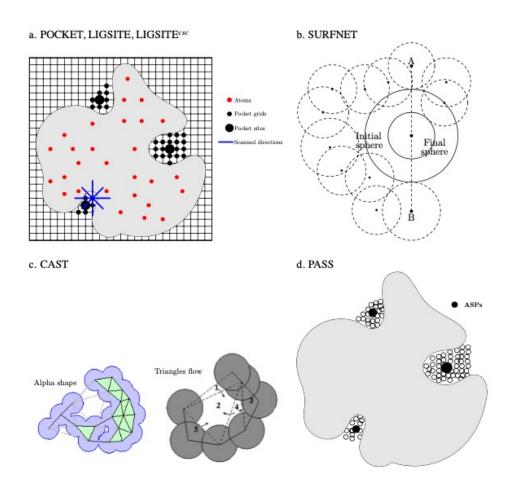

Finding a pocket

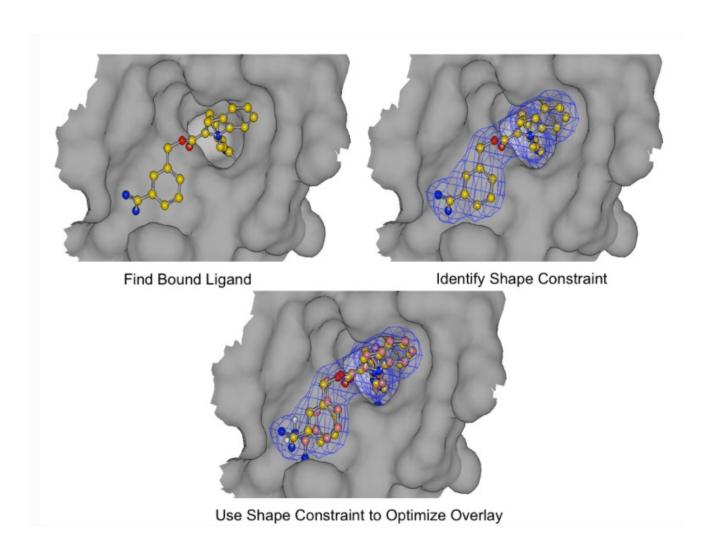

Using a reference atomic structure with an existing molecule bound

Using a pocket finding algorithm

Shape based methods

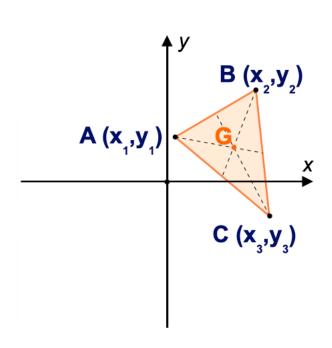

With an existing ligand it is possible to match the shape and optimize the overlay

Fast and robust

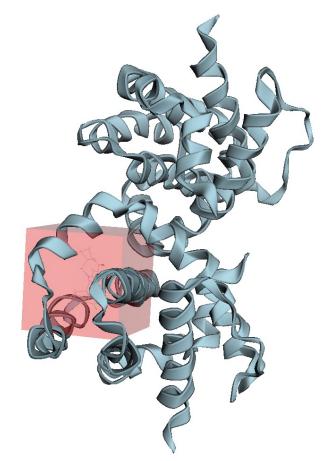

Ligand changes are not taken into account

Finding the docking grid area

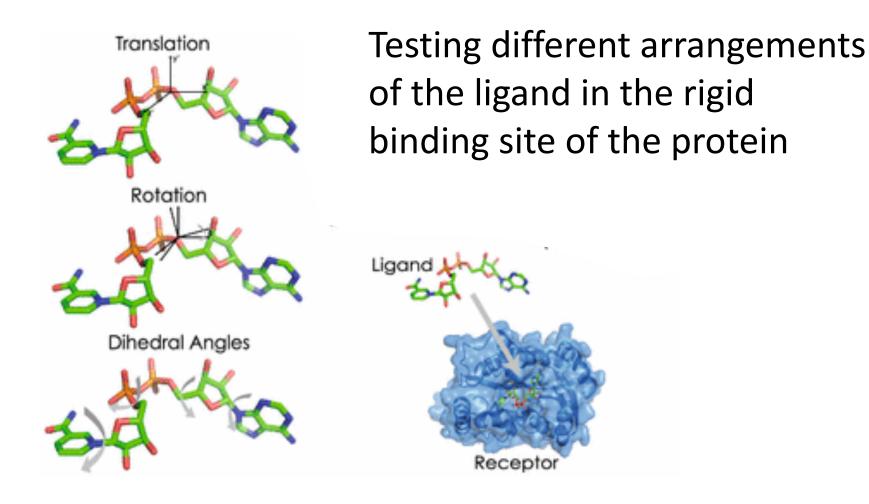

Often you have a ligand template or binding site residue to help with designing the docking grid

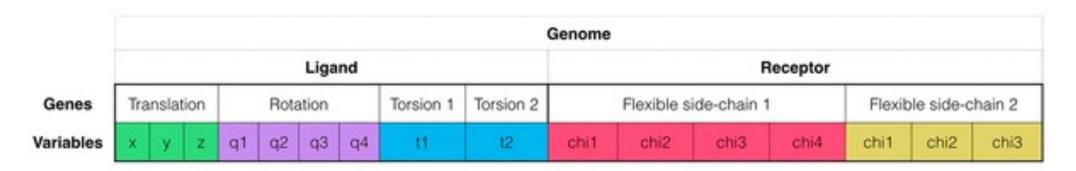

Use centre of geometry of a molecule from X-ray

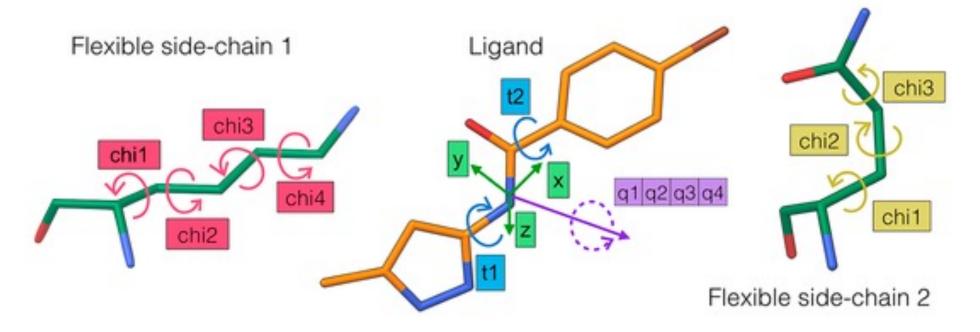

Genetic algorithm for ligand conformers

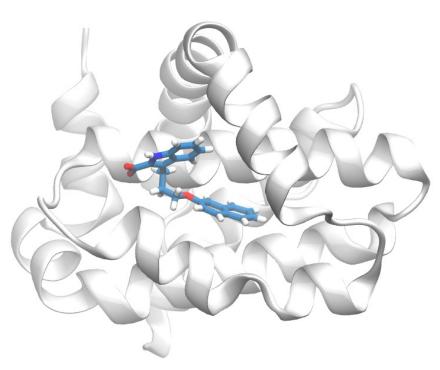

Allowing protein and ligand flexibility is often better

Flexibility increases compute time

N=T360/i

N: number of conformations

T: number of rotable bonds

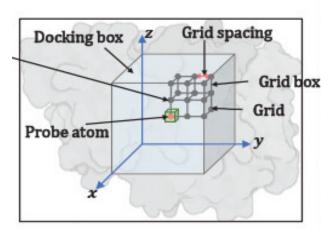

I: incremental degrees

Typical drug molecule

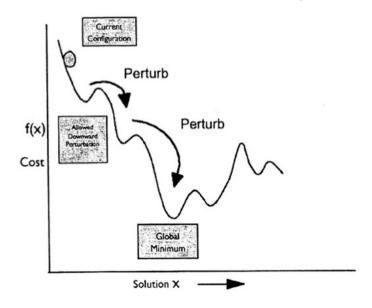

10 rotable bonds

30° increments (discrete)

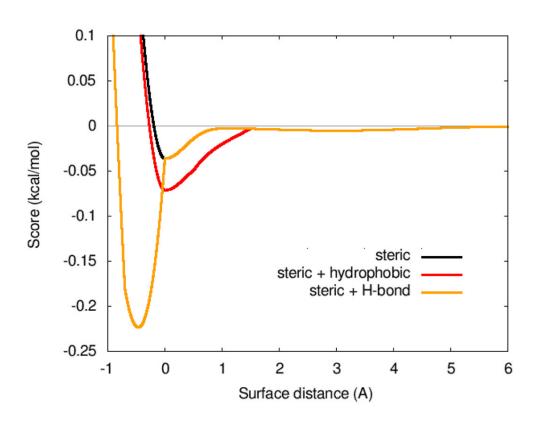

10¹² plausible conformations!

Simulated annealing

Scoring functions

Scoring functions can be used beyond shape optimization to optimize ligand and protein interactions

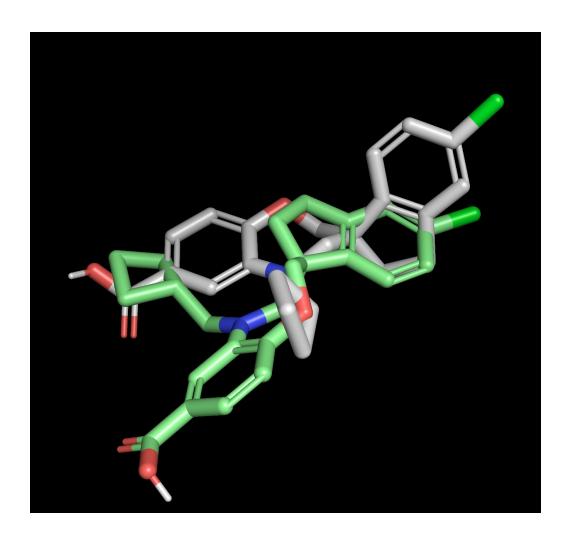

$$\Delta G = \left(V_{bonded}^{L-L} - V_{unbonded}^{L-L}\right) + \left(V_{bonded}^{R-R} - V_{unbonded}^{R-R}\right) + \left(V_{bonded}^{R-L} - V_{unbonded}^{R-L} + \Delta G_{conf}\right)$$

$$egin{align} V &= W_{vdw} \sum_{i,j} \left(rac{A_{ij}}{r_{ij}^{12}} - rac{B_{ij}}{r_{ij}^{6}}
ight) \ &+ W_{hbond} \sum_{i,j} E(t) \left(rac{C_{ij}}{r_{ij}^{12}} - rac{D_{ij}}{r_{ij}^{10}}
ight) \ &+ W_{elec} \sum_{i,j} rac{q_{i}q_{j}}{\epsilon(r_{ij})r_{ij}} \ &+ W_{sol} \sum_{i,j} (S_{i}V_{j} + S_{j}V_{i}) e^{rac{-r_{ij}^{2}}{2\sigma^{2}}} \ \end{aligned}$$

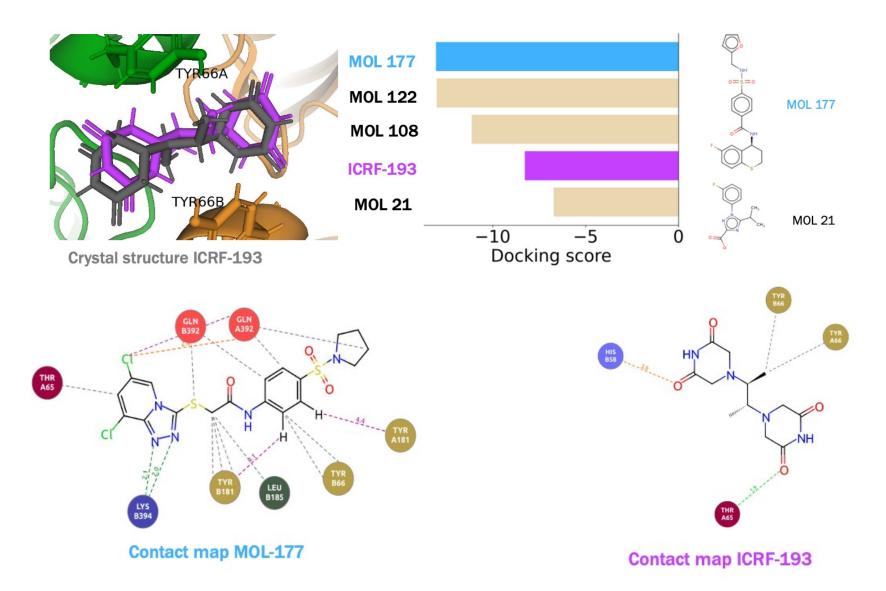

$$\Delta G_{conf} = W_{conf} N_{tors}$$

Typical docking output generates multiple poses

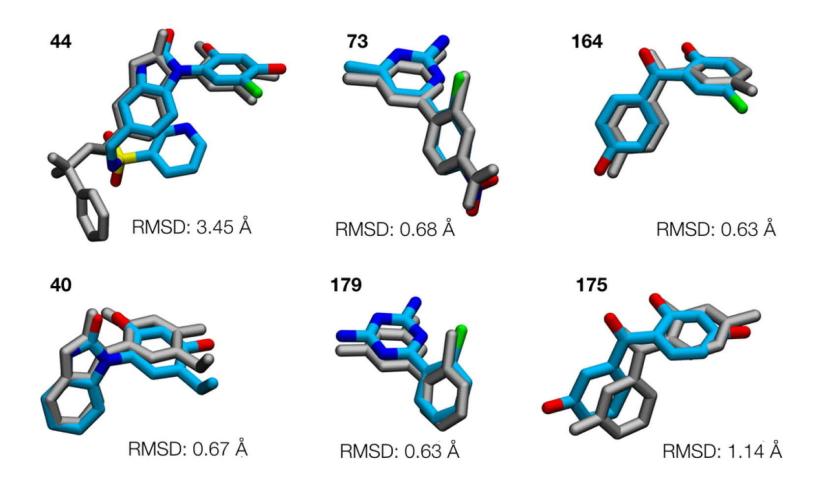

| mode | affinity (kcal/mol) | • | |
|------|--------------------------|-------|-------|
| 1 | -8 . 36 | 0 | 0 |
| 2 | -8.08 | 2.899 | 6.789 |
| 3 | -7 . 985 | 3.643 | 7.852 |
| 4 | -7.914 | 3.415 | 5.21 |
| 5 | -7.765 | 2.167 | 2.826 |

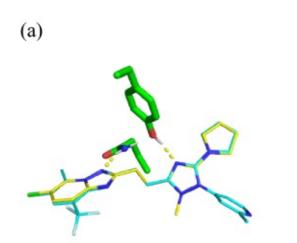

Evaluating Docked structures

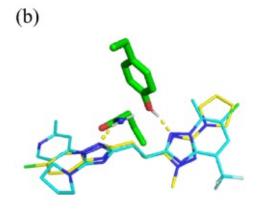

Evaluating the binding mode/pose

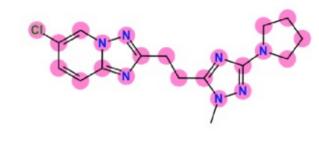

Template docking and cross docking improves docking

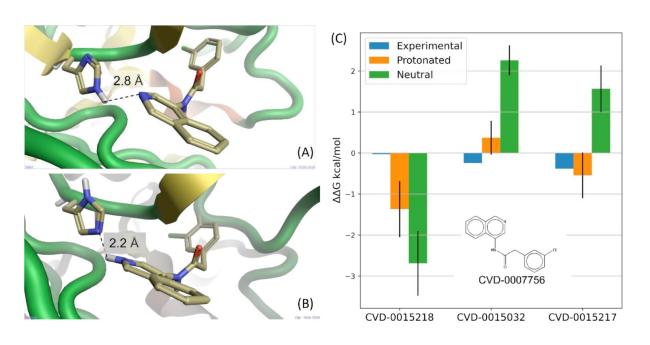

- (c) Ligand compound 40:
- (d) Template compound PDB code 5sej:

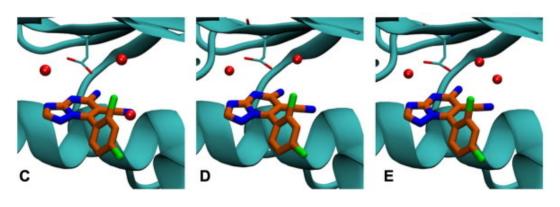

- Dock the same ligand into multiple protein structures (X-ray, MD)
- Generate multiple ligand conformers and dock into multiple structures
- Use existing ligand data as a template or guide e.g. through Maximum common substructure

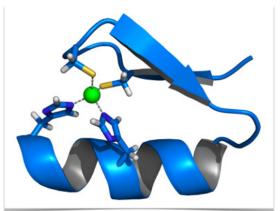

Things to worry about

pKa of ligands and binding site protonation need to be considered

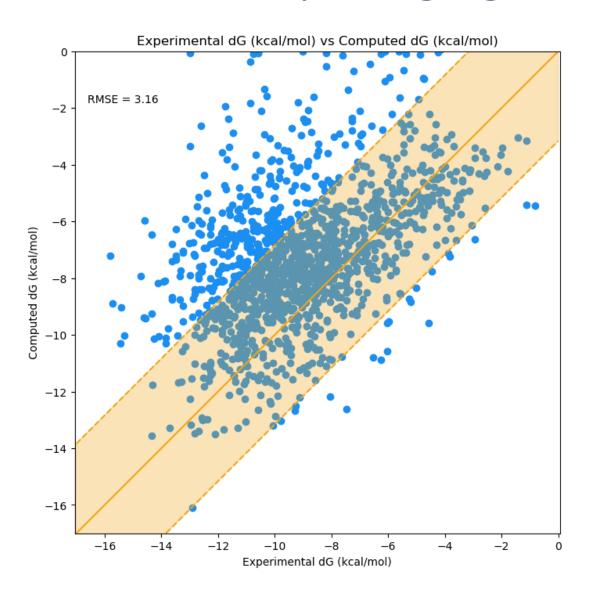

Structural waters are important

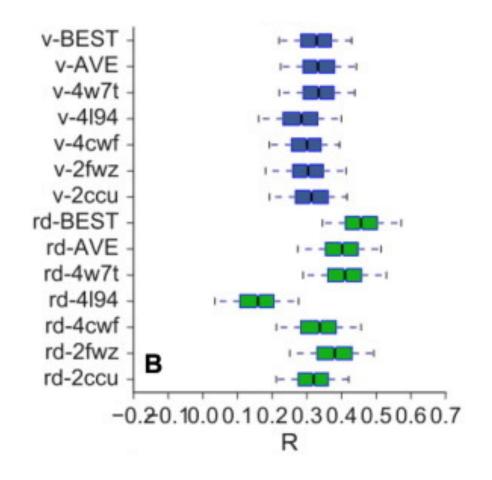

Co-factors such as ions and other molecules are imporant

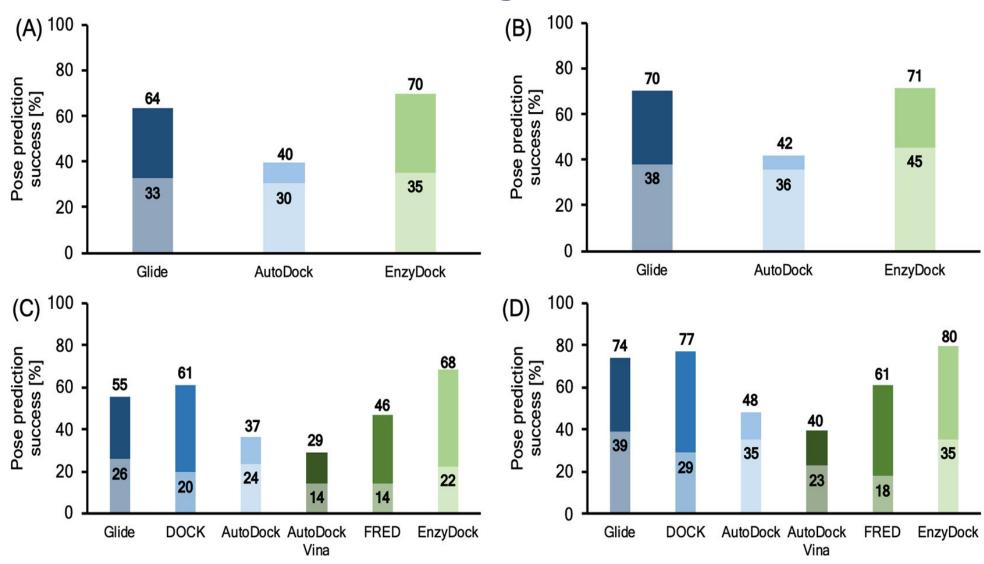

Comparing against experimental ΔG

Bulk assessment of correlation coefficient

Recent docking benchmark

What tools exist for molecular docking?

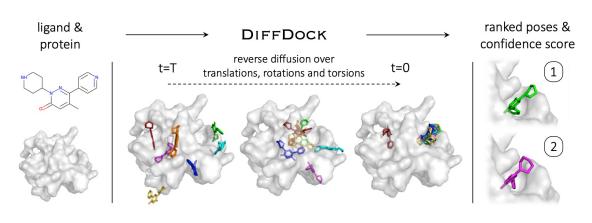

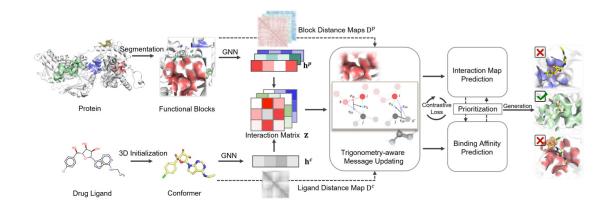

And others....

ML-based docking

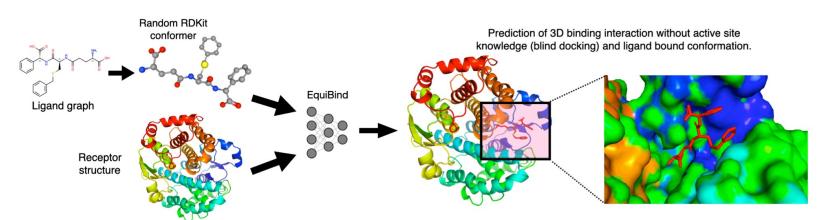

Diffdock

TankBind

Equibind

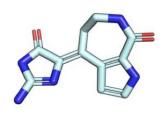

Gnina

Deepdock
