## Features are possible ways to represent data

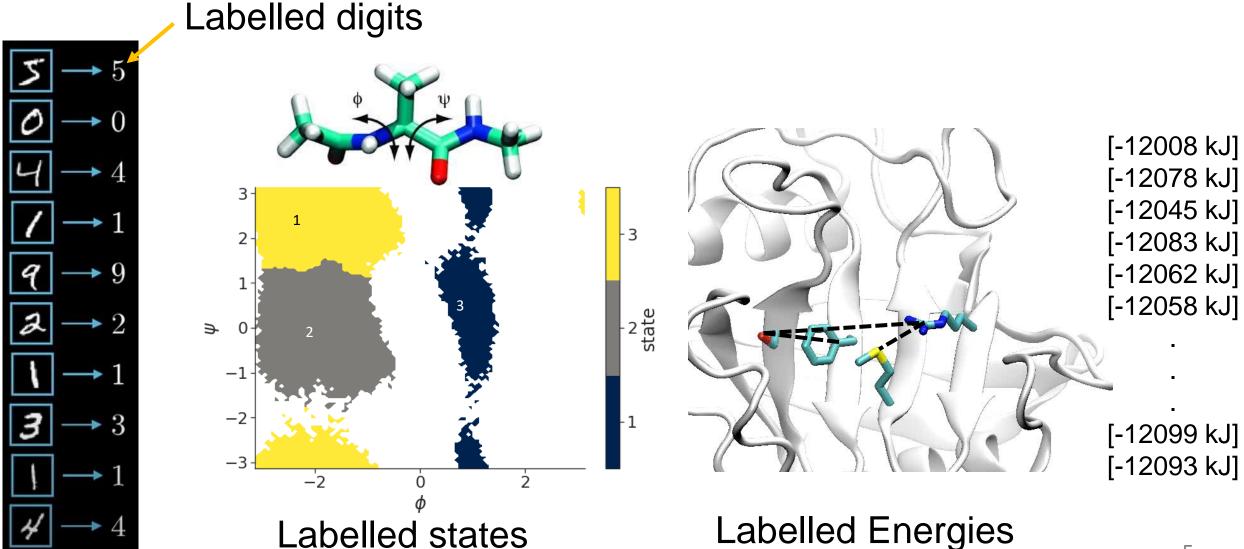

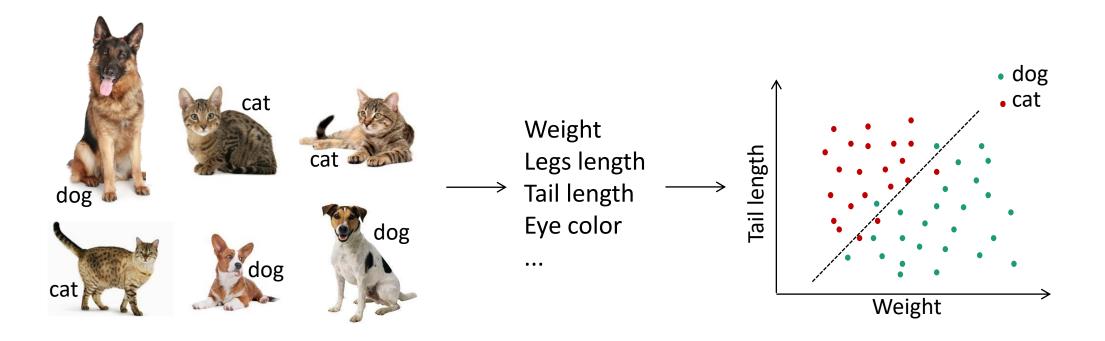

Interactomic distances

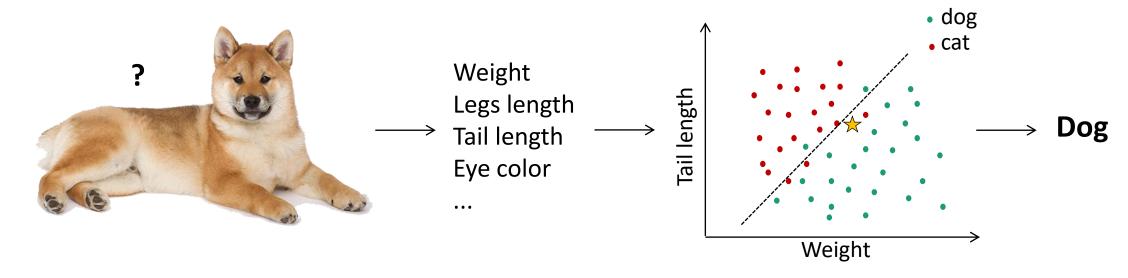

## Labels assign featurised data to categories

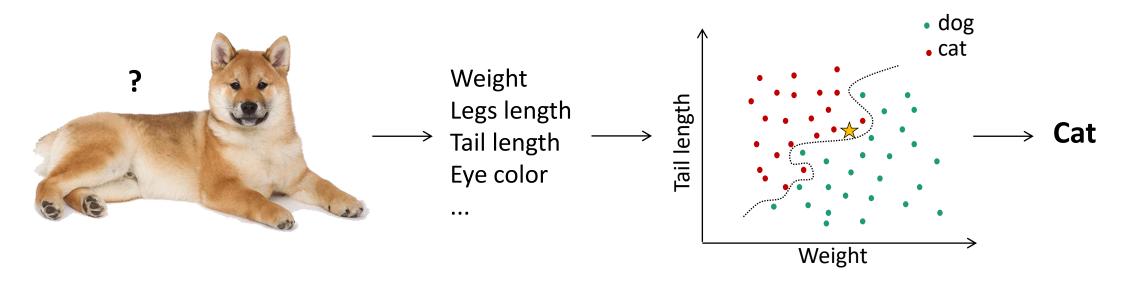

- take labelled data
- create an n-dimensional feature vector from data
- Separate «feature space» in different regions

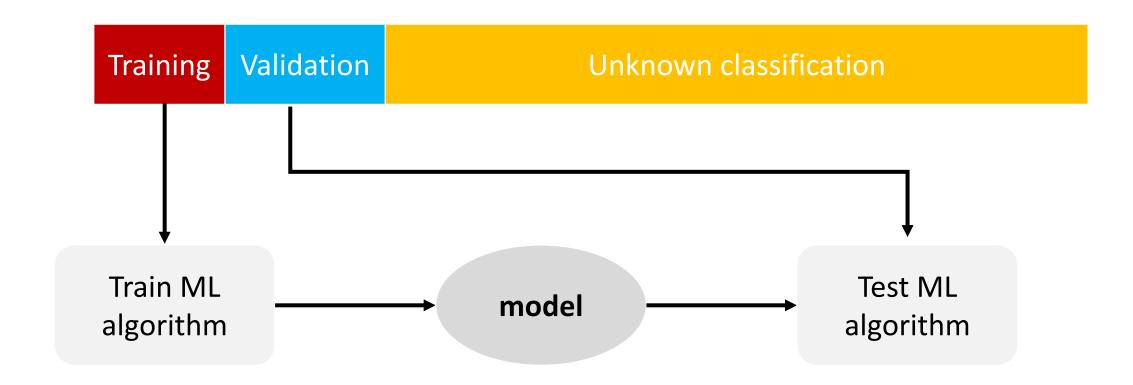

- take labelled data
- create an n-dimensional feature vector from data
- Separate «feature space» in different regions

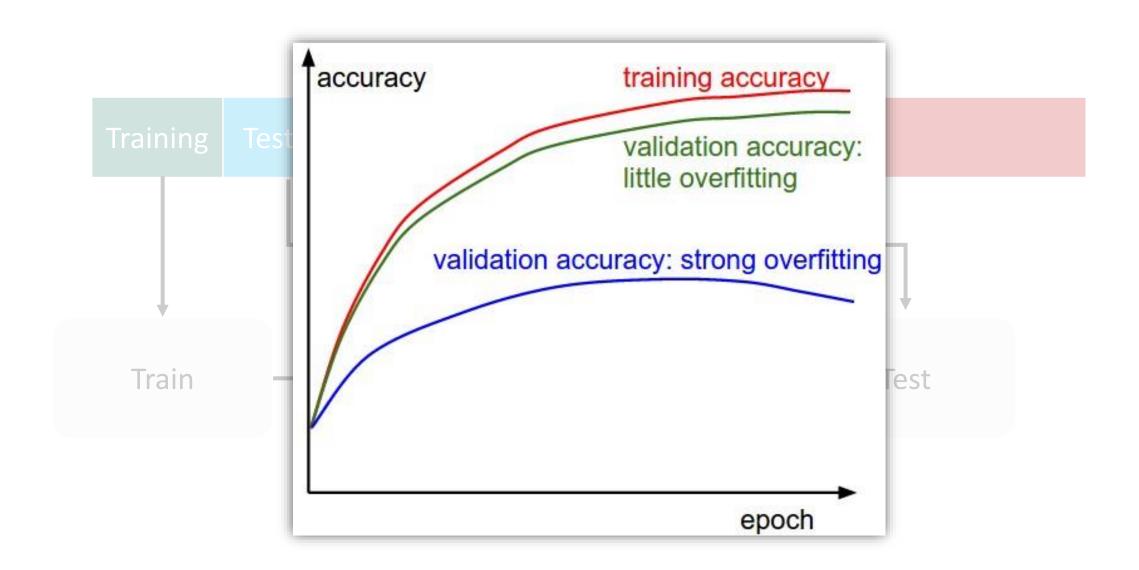

- take labelled data
- create an n-dimensional feature vector from data
- Separate «feature space» in different regions
- Warning: a too precise classification of examples might sacrifice generality (overfitting)

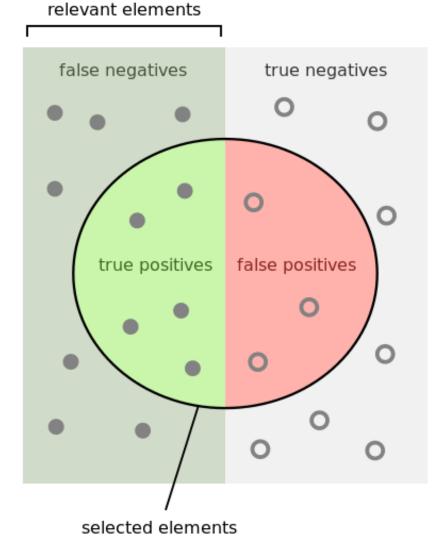

Data

### Some terminology

**Confusion Matrix:** describes classification results can also describe n classes

		Dog	Cat		
ובאפור	Dog	90	10		
	Cat	12	88		

real

• **precision** = 
$$\frac{\text{true positives}}{\text{selected elements}} = \frac{1}{1}$$

• sensitivity = recall = 
$$\frac{\text{true positives}}{\text{relevant elements}} = \frac{1}{100}$$

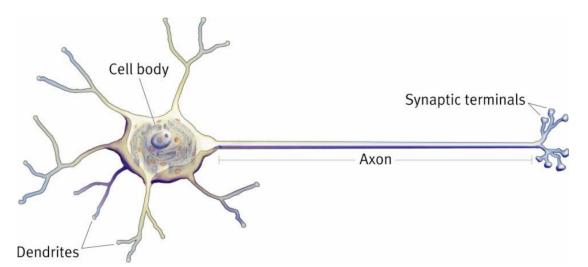

• 
$$accuracy = \frac{true positives + true negatives}{total population}$$

#### Learning Algorithms

- Artificial Neural Network (ANN)
- Decision Tree (DT)
- Random Forests (RF)
- Support Vector Machine (SVM)
- Logistic Regression (LOGRES)
- Naïve Bayes (NB)
- K Nearest Neighbor (KNN)
- ...

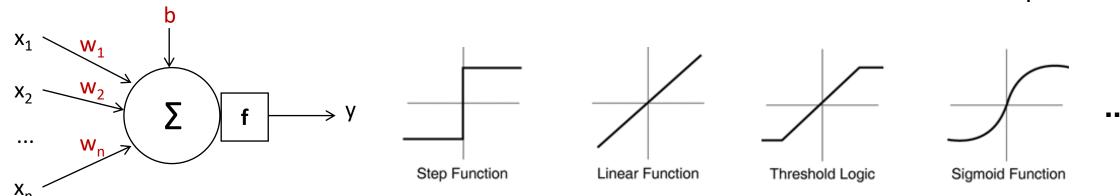

#### Learning Algorithms

- Artificial Neural Network (ANN)
- Decision Tree (DT)
- Random Forests (RF)
- Support Vector Machine (SVM)
- Logistic Regression (LOGRES)
- Naïve Bayes (NB)
- K Nearest Neighbor (KNN)
- ...

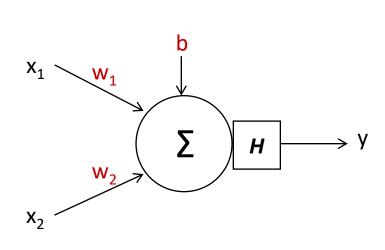

A **neuron** fires if input signal is above a threshold

The activation function **f** can take several shapes

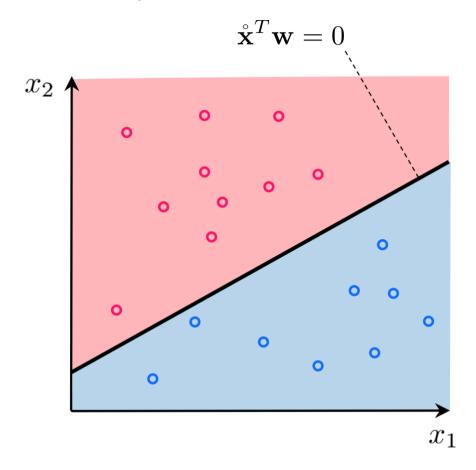

$$f(w_1x_1 + w_2x_2 + ... + w_nx_n + b) = y$$

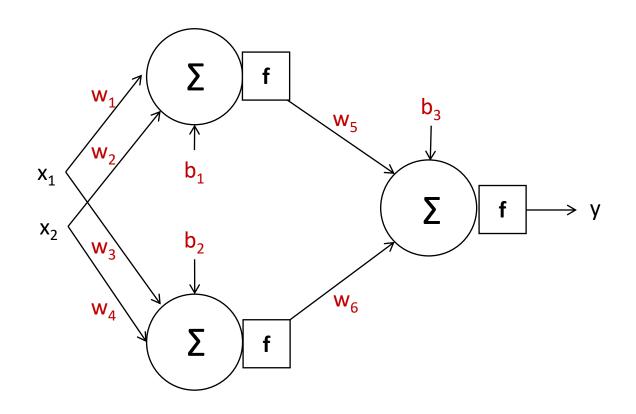

A single neuron can be used to take simple decisions

$$H(w_1x_1 + w_2x_2 + b) = y$$

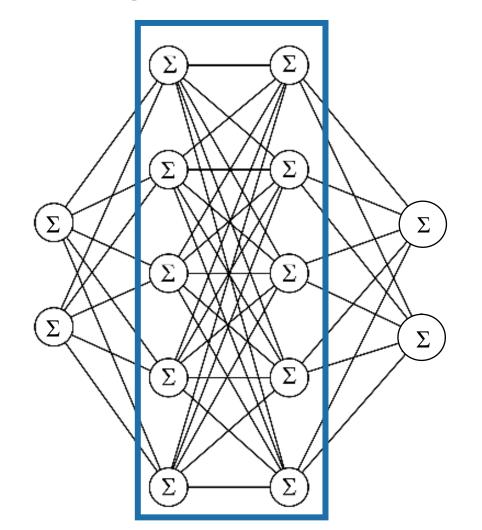

A single neuron can be used to take simple decisions

Complex decision making emerges when arranging neurons into **networks** 

A single neuron can be used to take simple decisions

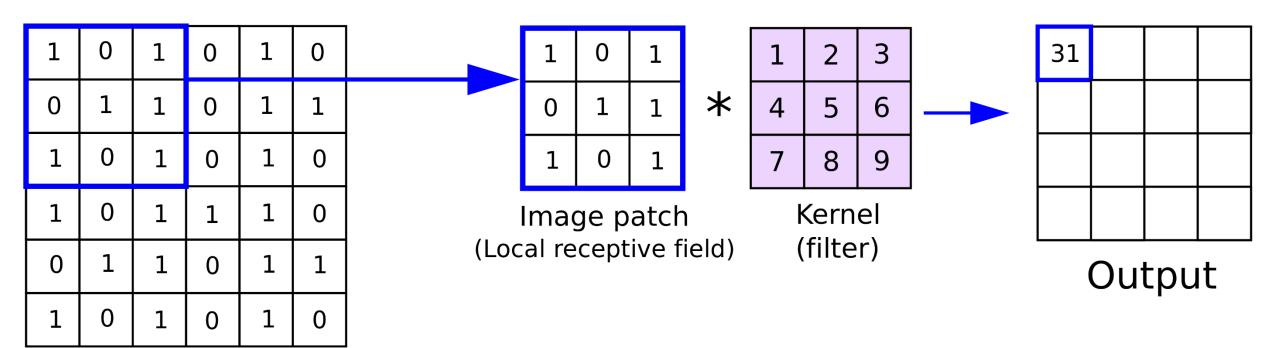

Complex decision making emerges when arranging neurons into **networks** 

An ANN with one hidden layer can approximate any function

## [Extra] Convolutional neural networks (CNN)

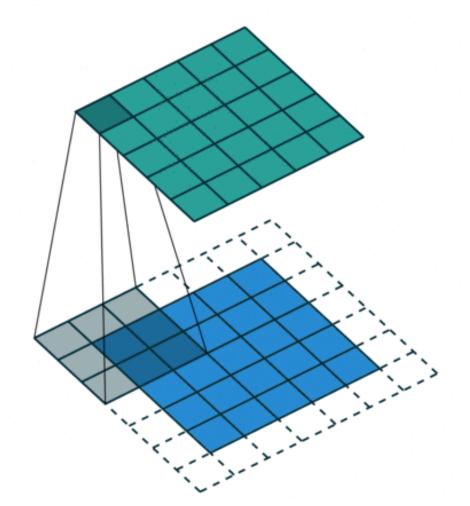

**Convolution**: a mathematical operation, "sliding a kernel" (filter) over the signal.

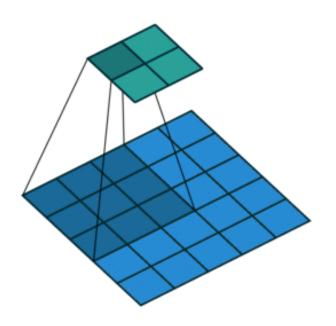

Input

## [Extra] Convolutional neural networks (CNN)

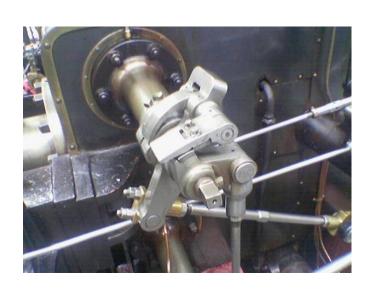

**Convolution**: a mathematical operation, "sliding a kernel" (filter) over the signal.

#### [Extra] Convolutional neural networks

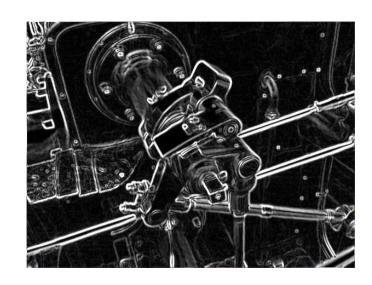

Convolution: a mathematical operation, "sliding a filter" (kernel) over the signal. Example, edge detection:

$$\mathbf{G}_x = egin{bmatrix} -1 & 0 & +1 \ -2 & 0 & +2 \ -1 & 0 & +1 \end{bmatrix} * \mathbf{A}$$

and

$$\mathbf{G}_y = egin{bmatrix} +1 & +2 & +1 \ 0 & 0 & 0 \ -1 & -2 & -1 \end{bmatrix} * \mathbf{A}$$

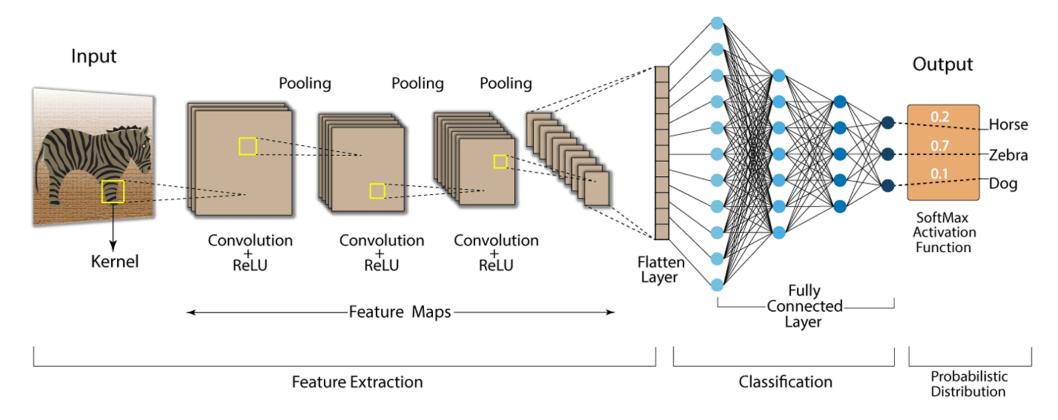

Convolutional neural network: instead of neurons, has many kernels. Learning = optimising kernel weights

#### [Extra] Convolutional neural networks

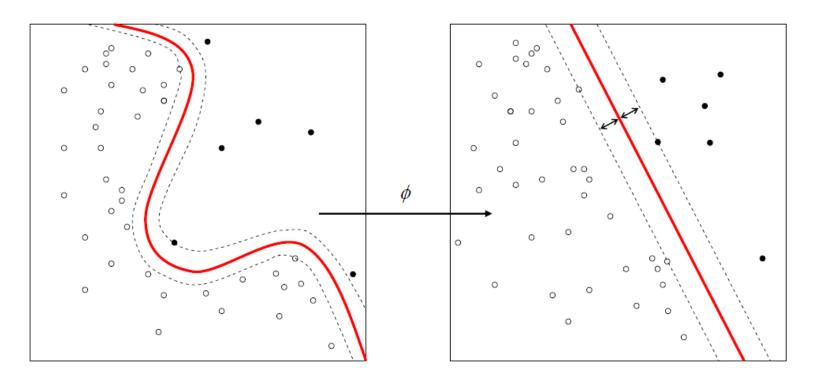

Exploit local correlation in data (e.g. Images, spectra, ...).

Can deal with inputs of arbitrary sizes with less parameters to learn

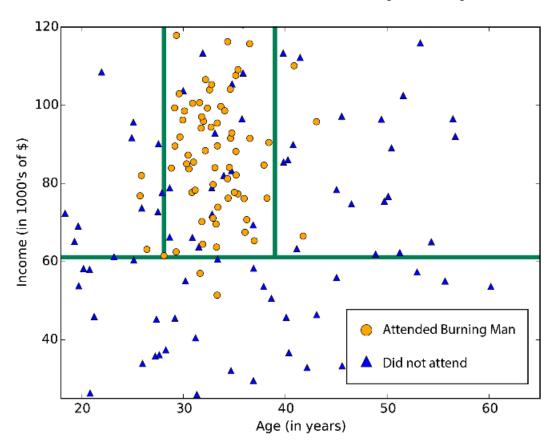

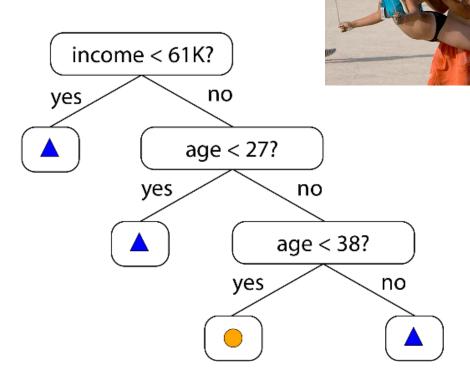

### [Extra] Support Vector Machine (SVM)

- invented by V. Vapnik et al. in the 1970s in Russia, but only known to the West in 1992
- linear classifier finding a hyperplane to separate two class of data
- **Kernel functions** ( $\Phi$ ) used for nonlinear separation

#### Decision Trees (DT)

- Subdivides features space in sectors
- Can overfit if space subdivision becomes too fine

## Bootstrap Aggregating (Bagging)

#### a weighted sum of weak classifiers creates a single strong classifier

Useful when a small change to training set causes large change in the output classifier ("learner is unstable")

Create *N* bootstrap samples S drawing *m* random examples from *D* with replacement

$$S[0]=$$
 5 1 7 2 7 9 2 6 5  $\rightarrow$ C[0]  
 $S[1]=$  9 4 7 1 2 8 9 7 6  $\rightarrow$ C[1]

$$S[2]= 0 8 2 0 9 7 7 0 1 \rightarrow C[2]$$

• • •

$$S[N] = 1 2 3 4 5 6 7 8 9 \rightarrow C[N]$$

**Training**: for every S, build a distinct classifier C using the same learning algorithm

### [Extra] Boosting

 a weighted sum of weak classifiers creates a single strong classifier

 iteratively add classifiers to a pool, tweaked to give more importance to data misclassified by previous classifiers

Weights based on learners accuracy

#### Random Forests (RF)

- Data bagging: creates N decision trees trained on bagged data
- Feature bagging: Given M features, every tree learns on m<M randomly selected features</li>
- Classification based on voting of resulting forest

#### Advantages:

- does not overfit
- Can handle thousands of features
- estimates what variables are important for classification

#### How do I pick the best learning algorithm?

Learning algorithms quality criteria:

- accuracy: percentage of correct classification
- robustness: handling noise and missing values
- efficiency: time to construct and use the model
- scalability: efficiency in memory requirements
- interpretability: how much the model is understandable

## [Extra] Accuracy and robustness benchmark (1)

R. Caruana et al. systematically tested learning algorithms against different datasets

#### Conclusion

 Know what algorithms do, what their limitations are, and how their parameters may affect results

Pick your algorithm depending on the nature of your data

Better data often beats better algorithms

Getting started: consider Python!
